## Measuring Galvanic Skin Response

Galvanic Skin Response (GSR) is the property of the human body that causes continuous variation in the electrical characteristics of the skin. The traditional theory of GSR holds that skin resistance varies with the state of sweat glands in the skin. Sweating is controlled by the sympathetic nervous system, and skin conductance is an indication of psychological or physiological arousal. If the sympathetic branch of the autonomic nervous system is highly aroused, then sweat gland activity also increases, which in turn increases skin conductance. In this way, skin conductance can be a measure of emotional and sympathetic responses. Examples of possible electrode placement and use of GSR in lie detection are shown below.

Design, conduct and analyze results of an experiment to develop a lie detection device based on GSR. Make sure to adhere to electrical safety constraints in your design.

## General Requirements

- 1. Experimental <u>Design</u> procedure including all requirements of Assessment Rubrics must be ready and approved by Lab Engineer before conducting any experiment.
- 2. All students must <u>Conduct</u> the experiment and document it according to the requirements of Assessment Rubrics and approved by Lab Engineer after conducting any experiment.
- 3. You are free to select any components you prefer for your experiments.
- 4. You should be prepared to demonstrate your experimental setup and answer questions in all aspects related to your experiment.
- 5. You should work in groups of 2 students each. One report addressing all parts of Assessment Rubrics should be submitted on behalf of the whole group.
- 6. You may use any resources you find useful to your experiment as long as you acknowledge such use in your report in accordance to ethical guidelines.
